ACKNOWLEDGMENTS

First, I thank my thesis advisor, David Tirrell, for his guidance and support. He generously shared with me his scientific insight, strong sense of purpose and integrity, and thoughtful counsel. Our many interesting discussions, about matters both scientific and otherwise, have helped me immensely in my scientific and personal development.

I would also like to thank my thesis committee, Anand Asthagiri, Mark Davis, and Barbara Wold, for their valuable advice and comments. I also thank Profs. Tetsuji Yamaoka and Rob Phillips for providing me with personal guidance and scientific enthusiasm. As I embark on my own scientific career, I am fortunate to have such excellent role models.

The many members of the Tirrell Group, past and present, have been wonderful colleagues. Our daily interactions made life inside and outside of the lab enjoyable. Thank you all for your friendship and scientific creativity.

Several members of the Caltech community have provided me with continuous support and understanding. Thank you to the WEST steering committee, the supportive Caltech staff, and the faculty who have taken time to participate in our activities. My interactions with all of you have greatly enhanced my graduate school experience.

Thank you to my friends, both at Caltech and around the world. Your encouragement has kept me both focused and balanced.

My family has been the foundation of my success. Their never-failing love and faith in me has given me the confidence to pursue my dreams.

Finally, thank you to my fiancé, Andrew Spakowitz, for his friendship, love, honesty, and trust.

ABSTRACT

Design and Characterization of Artificial Extracellular Matrix Proteins

for Use as Small-Diameter Vascular Grafts

May 2004

Sarah Heilshorn, B.S., Georgia Institute of Technology

M.S., California Institute of Technology

Ph.D. California Institute of Technology

Synthetic small-diameter vascular grafts often fail within three years of implantation. The underlying causes of graft failure are thought to be i) a mismatch in the mechanical properties between the graft and host material and ii) an inability of the graft to support the adhesion of endothelial cells. To address these two issues, artificial extracellular matrix (aECM) proteins contain elastin-like regions to provide physical integrity and cell-binding domains derived from fibronectin to promote endothelial cell attachment. Using recombinant protein technology, a family of artificial proteins was created with differing ratios of elastin-like regions to cell-binding domains, with variable placement of amino acid crosslinking residues, and with differing identity of cell-binding domain.

Human umbilical vein endothelial cells (HUVEC) adhere in a sequence-specific manner to aECM proteins, secrete basal levels of key fibrinolytic regulators, and are capable of resisting a physiologically relevant detachment force. HUVEC spread more quickly and adhere more firmly to aECM proteins that contain the RGD versus the CS5 cell-binding domain. Decreasing the density of RGD cell-binding domains results in

decreased HUVEC adhesion. Furthermore, amino acid selection even at sites up to 16 residues away from the cell-binding domain impacts HUVEC spreading and adhesion. HUVEC also adhere more strongly to stiffer aECM films. Therefore, the identity, density, and context of the cell-binding domain as well as the elastic modulus of the substrate are all important variables in influencing cell-substrate interactions.

Proper amino acid sequence choice also influences the susceptibility of aECM proteins to elastase proteolysis; modifying 3% of the amino acid side chains results in a 7-fold reduction in degradation rate. An alternative strategy to decrease degradation involves incorporation of the noncanonical amino acid, 5,5,5-trifluoroisoleucine, into the favored proteolytic cut site, isoleucine. Replacing 82% of the isoleucines results in a twofold reduction in degradation rate without compromising sequence-specific HUVEC adhesion. Incorporation of another noncanonical amino acid, *para*-azidophenylalanine, allows synthesis of photoreactive proteins that can be patterned using photolithography. These protein patterns retain their ability to adhere HUVEC and produce stable cell patterns after 48 hours in medium supplemented with serum.

ABBREVIATIONS

5TFI	5,5,5-trifluoroisoleucine
aECM	Artificial extracellular matrix protein
BCA	Bicinchoninic acid
BS3	Bis(sulfosuccinimidyl) suberate
BSA	Bovine serum albumin
CAI	Cell adhesion index
DPN	Dip-pen nanolithography
E	Elastic modulus
ECM	Extracellular matrix
ePTFE	expanded poly(tetrafluoroethylene)
ELISA	Enzyme-linked immunosorbent assay
HLE	Human leukocyte elastase
HMDI	Hexamethylene diisocyanate
HUVEC	Human umbilical vein endothelial cells
LAL	<i>Limulus</i> ameocyte lysate gel-clot assay
LCST	Lower critical solution temperature
LPS	Lipopolysaccharide
MALDI-MS	Matrix-assisted laser desorption ionization-mass spectrometry
M_c	Molecular weight between crosslinks
PAI-1	Plasminogen activator inhibitor
PBS	Phosphate buffered saline
PET	Poly(ethylene terephthalate)
pN₃Phe	<i>Para</i> -azidophenylalanine
SDS-PAGE	Sodium dodecyl sulfate - polyacrylamide gel electrophoresis
SEM	Scanning electron microscopy
tPA	Tissue plasminogen activator
TSAT	Tri-succinimidyl aminotriacetate

Note: Single letter abbreviations for the natural amino acids are listed in Appendix A.
