51. It is not apparent that in the crystal-like state the probabilities of the three non-preferred orientations should be equal as there is not a symmetry breaking event in the direction transverse to the lamella direction. However our calculations found that this assumption holds for all temperatures.

77. This argument is based on an exchange dynamics for the lattice. However, a flip (rotation) dynamics (as employed here in the DMF) would yield the same result. With a concentration of unpaired molecules being  $\exp(-\beta\epsilon)$ , the probability that a randomly chosen satisfied molecule is turned into an unpaired one in unit time is

- simply  $\omega \exp(-\beta\epsilon)$ . The time it takes for the lattice to relax is such that  $\tau \omega \exp(-\beta\epsilon) \sim 1$ , or  $\tau \sim \omega^{-1} \exp(\beta\epsilon)$ .

114. Each vertex has four edges along which bonds may form. The probability that there is a bonding site from the monomer along a specific edge is  $3/4$ ; in the limit of high temperature there is no correlation in orientation of neighboring monomers. Each bond is shared by two monomers. This results in  $4 \times 3/4 \times 3/4 \times 1/2 = 9/8$  bonds/vertex.
